XmlFindChild

This function returns a named child node of an XML node.

Syntax

```
xmlnode xmlFindChild ( xmlnode parent, string tagName, int index )
```

OOP Syntax Help! I don't understand this!

Method: *xmlnode:findChild(...)*

Required Arguments

- **parent**: This is an xmlnode that you want to find the child node under.
- **tagName**: This is the name of the child node you wish to find (case-sensitive).
- **index**: This is the 0-based index of the node you wish to find. For example, to find the 5th subnode with a particular name, you would use 4 as the index value. To find the first occurence, use 0.

Returns

Returns an xmlnode if the node was found, *false* otherwise.
