Gettok

This function splits a string using the given separating character and returns one specified substring.

Syntax

```
string gettok ( string text, int tokenNumber, string / int separatingCharacter )
```

Required Arguments

- **text:** the string that should be split.
- **tokenNumber:** which token should be returned (1 for the first, 2 for the second, and so on).
- **separatingCharacter:** the ASCII number representing the character you want to use to separate the tokens. You can easily retrieve this by running string.byte on a string containing the separating character.

Returns

Returns a string containing the token if it exists, *false* otherwise.
